

Use FTXui c++ library to create a very simple, running tui that I can use to bootstrap my own application.

Goals

1. put the correct `add_requires` statement in `xmake.lua` so that `xmake` downloads, installs and builds the package.
2. create the `cpp` file `tui_example.cpp` to hold the function `main` and all of the other functions you need to create.
3. modify the “this” `xmake.lua` target to build the tui.
4. use the commands and descriptions in `commands.md` for the commands and 1 line descriptions to create a menu accessible with `/`.
5. use the help topics and help text in `help.md` to create the code that will display the help topics and allow selection of the topic to display the help text. this will be the implementation of the `help` command.
6. each of the other commands has a trivial stub implemented in the corresponding `cpp` files that can be wired into executing each command.
7. Follow the style of the TUI screen shots I have shown in the `.png` files in the `scratch/tui` directory.

Task completion

- make sure the code builds with `xmake` successfully
- run the code and check the screen display is correct (if you can...)

Here are some details for the screen shots:

Opening Screen

- Don't use graphic block characters for the title: just centered bold text: `epi_sim\n Epidemic Simulation Model`
- in the center prompt box the initial text should be `Press slash for commands to get started` and below that “Suggestion: choose `/help` followed by selecting `Get started...`
- nothing immediately below the prompt box
- no tip
- at bottom left: the working directory
- at bottom right: we will display the case tag, but we don't have one set so the default “null” text is: `No case selected...`

Post command output

- pretty much as you see it: the output scrolls continuously

- the prompt box is always at the bottom and displays prompts produced by the running code or just put Press slash to choose a command... in grayed text
- nothing below the prompt box
- create the sidebar even though we don't have anything much to put in it yet
 - Title: Case <>
 - first heading Population (later application code will provide things to fill in)
 - second heading: Output (nothing until application code fills it in)
 - third heading: Plots (ditto)
 - footer text: working directory

Menu for command at intro screen

- pretty much as shown
- line below menu should say either "Available commands..." if the / shows the top level menu or it should show the previous command: for example if help was the command chosen then line below the menu should say "Available help topics..." this string should be a variable, possibly part of a struct MenuDisplay
- footer as before
